

A boundary between universality and non-universality in spiking neural P systems¹

Turlough Neary

Abstract

In this work we offer a significant improvement on the previous smallest spiking neural P systems and solve the problem of finding the smallest possible extended spiking neural P system. Păun and Păun [15] gave a universal spiking neural P system with 84 neurons and another that has extended rules with 49 neurons. Subsequently, Zhang et al. [18] reduced the number of neurons used to give universality to 67 for spiking neural P systems and to 41 for the extended model. Here we give a small universal spiking neural P system that has only 17 neurons and another that has extended rules with 5 neurons. All of the above mentioned spiking neural P systems suffer from an exponential slow down when simulating Turing machines. Using a more relaxed encoding technique we get a universal spiking neural P system that has extended rules with only 4 neurons. This latter spiking neural P system simulates 2-counter machines in linear time and thus suffer from a double exponential time overhead when simulating Turing machines. We show that extended spiking neural P systems with 3 neurons are simulated by log-space bounded Turing machines, and so there exists no such universal system with 3 neurons. It immediately follows that our 4-neuron system is the smallest possible extended spiking neural P system that is universal. Finally, we show that if we generalise the output technique we can give a universal spiking neural P system with extended rules that has only 3 neurons. This system is also the smallest of its kind as a universal spiking neural P system with extended rules and generalised output is not possible with 2 neurons.

Key words: spiking neural P systems, small universal spiking neural P systems, computational complexity, strong universality, weak universality

1. Introduction

Spiking neural P systems (SN P systems) [5] are quite a new computational model that are a synergy inspired by P systems and spiking neural networks. It has been shown that these systems are computationally universal [5]. Recently, Păun and Păun [15] gave two small universal SN P systems; They give an SN P system with 84 neurons and an extended SN P system with 49 neurons (that uses rules without delay). Păun and Păun conjectured that it is not possible to give a significant decrease in the number of neurons of their two universal systems. Zhang et al. [18] offered such a significant decrease in the number of neurons used to give such small universal systems. They give a universal SN P system with 67 neurons and another, which has extended rules (without delay), with 41 neurons. Here we give a small universal SN P system that has only 17 neurons and another, which has extended rules (without delay), with 5 neurons. Using a more relaxed encoding we get a universal SN P system that has extended rules (without delay), with 4 neurons. Table 1 gives the smallest universal SN P systems and their respective simulation time and space overheads. Note from Table 1 that, in addition to its small size, our 17-neuron system uses rules without delay. The other small universal SN P systems with standard rules [15,18] do not have this restriction.

In this work we also show that extended SN P systems with 3 neurons and generalised input are simulated by log-space bounded Turing machines. As a result, it is clear that there exists no such universal system with 3 neurons, and thus our 4-neuron system is the smallest possible universal extended SN P system. Following this, we show that if we generalise the output technique we can give a universal SN P system with extended rules that has only 3 neurons. In addition, we show that a universal SN P system with extended rules and generalised output is not possible with 2 neurons, and thus our 3-neuron systems is the smallest of its kind.

From a previous result [13] it is known that there exists no universal SN P system that simulates Turing machines in less the exponential time and space. It is a relatively straightforward matter to generalise this result to show that extended SN P systems suffer from the same inefficiencies. It immediately follows that the universal systems we present here and those found in [15,18] have exponential time and space requirements. However, it is possible to give a time efficient SN P system when we allow exhaustive use of rules. A universal extended SN P system with exhaustive use of rules has been given that simulates Turing machines in linear time [12]. Furthermore, this system has only 10 neurons. SN P systems with exhaustive use of rules were originally proved computationally universal by Ionescu et al. [4]. However, the technique used to prove universality suffered from an exponential time overhead.

Using different forms of SN P systems, a number of time efficient (polynomial or constant time) solutions to NP-hard problems have been given [2,8,9]. All of these solutions to NP-hard problems rely on families of SN P systems. Specifically, the size of the problem instance determines the number of neurons in the SN P system that solves that particular instance. This is similar to solving problems with circuits families where each input size has a specific circuit that solves it. Ionescu and Sburlan [6] have shown that SN P systems simulate circuits in linear time.

In Section 4 we give a definition for SN P systems, explain their operation and give other relevant technical details. In Section 3 we give a definition for counter machines and we also discuss some notions of universality. Following this, in Section 4 we give our small universal SN P systems and show how their size can be reduce if we use a more relaxed encoding. In Section 5 we give our proof showing that extended SN P systems with 3 neurons and generalised input are simulated by log-space bounded Turing machines. Section 5 also contains our universal 3-neuron system with generalised output. We end the paper with some discussion and conclusions.

Table 1

Small universal SN P systems. The “simulation time” column gives the overheads used by each system when simulating a standard single tape Turing machine. † indicates that there is a restriction of the rules as delay is not used and ‡ indicates that a more generalised output technique is used. *The 18 neuron system is not explicitly given in [14]; it is however mentioned at the end of the paper and is easily derived from the other system presented in [14]. Also, its operation and its graph were presented in [11].

2. SN P systems

Definition 1 (Spiking neural P system)

A *spiking neural P system* (SN P system) is a tuple $\Pi = (O, \sigma_1, \sigma_2, \dots, \sigma_m, \text{syn}, \text{in}, \text{out})$, where:

- (i) $O = \{s\}$ is the unary alphabet (s is known as a spike),
- (ii) $\sigma_1, \sigma_2, \dots, \sigma_m$ are neurons, of the form $\sigma_i = (n_i, R_i)$, $1 \leq i \leq m$, where:
 - (a) $n_i \geq 0$ is the initial number of spikes contained in σ_i ,
 - (b) R_i is a finite set of rules of the following two forms:
 - (i) $E/s^b \rightarrow s; d$, where E is a regular expression over s , $b \geq 1$ and $d \geq 0$,
 - (ii) $s^e \rightarrow \lambda$, where λ is the empty word, $e \geq 1$, and for all $E/s^b \rightarrow s; d$ from R_i $s^e \notin L(E)$ where $L(E)$ is the language defined by E ,
- (iii) $\text{syn} \subseteq \{1, 2, \dots, m\} \times \{1, 2, \dots, m\}$ is the set of synapses between neurons, where $i \neq j$ for all $(i, j) \in \text{syn}$,
- (iv) $\text{in}, \text{out} \in \{\sigma_1, \sigma_2, \dots, \sigma_m\}$ are the input and output neurons, respectively.

A firing rule $r = E/s^b \rightarrow s; d$ is applicable in a neuron σ_i if there are $j \geq b$ spikes in σ_i and $s^j \in L(E)$ where $L(E)$ is the set of words defined by the regular expression E . If, at time t , rule r is executed then b spikes are removed from the neuron, and at time $t + d$ the neuron fires. When a neuron σ_i fires a spike is sent to each neuron σ_j for every synapse (i, j) in Π . Also, the neuron σ_i remains closed and does not receive spikes until time $t + d$ and no other rule may execute in σ_i until time $t + d + 1$. A forgetting rule $r' = s^e \rightarrow \lambda$ is applicable in a neuron σ_i if there are exactly

e spikes in σ_i . If r' is executed then e spikes are removed from the neuron. At each timestep t a rule must be applied in each neuron if there is one or more applicable rules at time t . Thus, while the application of rules in each individual neuron is sequential the neurons operate in parallel with each other.

Note from 2b(i) of Definition 1 that there may be two rules of the form $E/s^b \rightarrow s; d$, that are applicable in a single neuron at a given time. If this is the case then the next rule to execute is chosen non-deterministically.

An *extended* SN P system [15] has more general rules of the form $E/s^b \rightarrow s^p; d$, where $b \geq p \geq 1$. Thus, a synapse in an SN P system with extended rules may transmit more than one spike in a single timestep. The SN P systems we present in this work use rules without delay, and thus in the sequel we write rules as $E/s^b \rightarrow s^p$. Also, if in a rule $E = s^b$ then we write the rule as $s^b \rightarrow s^p$.

In the same manner as in [15], spikes are introduced into the system from the environment by reading in a binary sequence (or word) $w \in \{0, 1\}^*$ via the input neuron σ_1 . The sequence w is read from left to right one symbol at each timestep and a spike enters the input neuron on a given timestep iff the read symbol is 1. The output of an SN P system Π is the time between the first and second firing rule applied in the output neuron and is given by the value $\Pi(w) \in \mathbb{N}$.

A configuration c of an SN P system consists of a word w and a sequence of natural numbers $(r_1, r_2, \dots, r_m)$ where r_i is the number of spikes in σ_i and w represents the remaining input yet to be read into the system. A computation step $c_j \vdash c_{j+1}$ is as follows: each number r_i is updated depending on the number of spikes neuron σ_i uses up and receives during the synchronous application of all applicable rules in configuration c_j . In addition, if $w \neq \lambda$ then the leftmost symbol of w is removed. A SN P system computation is a finite sequence of configurations $c_1, c_2, \dots, c_t$ that ends in a terminal configuration c_t where for all $j < t$, $c_j \vdash c_{j+1}$. A *terminal configuration* is a configuration where the input sequence has finished being read in via the input neuron (i.e. $w = \lambda$ the empty word) and either there is no applicable rule in any of the neurons or the output neuron has spiked exactly v times (where v is a constant independent of the input).

Let ϕ_x be the x^{th} n -ary partial recursive function in a Gödel enumeration of all n -ary partial recursive functions. The natural number value $\phi_x(y_1, y_2, \dots, y_n)$ is the result given by ϕ_x on input $(y_1, y_2, \dots, y_n)$.

Definition 2 [Universal SN P system] A SN P system Π is universal if there are recursive functions g and f such that for all $x, y \in \mathbb{N}$ we have $\phi_x(y_1, y_2, \dots, y_n) = f(\Pi(g(x, y_1, y_2, \dots, y_n)))$.

In the next section we give some further discussion on the subject of definitions of universality.

3. Counter machines

Definition 3 (Counter machine) A counter machine is a tuple $C = (z, R, c_m, Q, q_1, q_h)$, where z gives the number of counters, R is the set of input counters, c_m is the output counter, $Q = \{q_1, q_2, \dots, q_h\}$ is the set of instructions, and $q_1, q_h \in Q$ are the initial and halt instructions, respectively.

Each counter c_j stores a natural number value $y \geq 0$. Each instruction q_i is of one of the following two forms $q_i : INC(j), q_l$ or $q_i : DEC(j), q_l, q_k$ and is executed as follows:

- $q_i : INC(j), q_l$ increment the value y stored in counter c_j by 1 and move to instruction q_l .
- $q_i : DEC(j), q_l, q_k$ if the value y stored in counter c_j is greater than 0 then decrement this value by 1 and move to instruction q_l , otherwise if $y = 0$ move to instruction q_k .

At the beginning of a computation the first instruction executed is q_1 . The input to the counter machine is initially stored in the input counters. If the counter machine's control enters instruction q_h , then the computation halts at that timestep. The result of the computation is the value y stored in the output counter c_m when the computation halts.

We now consider some different notions of universality. Korec [7] gives universality definitions that describe some counter machines as weakly universal and other counter machines as strongly universal.

Definition 4 [Korec [7]] *A register machine M will be called strongly universal if there is a recursive function g such that for all $x, y \in \mathbb{N}$ we have $\phi_x(y) = \Phi_M^2(g(x), y)$.*

Here $\Phi_M^2(g(x), y)$ is the value stored in the output counter at the end of a computation when M is started with the values $g(x)$ and y in its input counters. Korec's definition insists that the value y should not be changed before passing it as input to M . However, if we consider computing an n -arry function with a Korec-strong universal counter machine then it is clear that n arguments must be encoded as a single input y . Many Korec-strong universal counter machines would not satisfy a definition where the function ϕ_x in Definition 4 is replaced with an n -arry function with $n > 1$. For example, let us give a new definition where we replace the equation " $\phi_x(y) = \Phi_M^2(g(x), y)$ " with the equation " $\phi_x^n(y_1, y_2, \dots, y_n) = \Phi_M^{n+1}(g(x), y_1, y_2, \dots, y_n)$ " in Definition 4. Note that for any counter machine M with r counters, if $r \leq n$ then M does not satisfy this new definition. It could be considered that Korec's notion of strong universality is somewhat arbitrary for the following reason: Korec's definition will admit machines that require n -arry input $(y_1, y_2, \dots, y_n)$ to be encoded as the single input y when simulating an n -arry function, but his definition will not admit a machine that applies an encoding function to y (e.g. y^2 is not permitted). Perhaps when one uses this notion of universality it would be more appropriate to refer to it as strongly universal for unary partial recursive functions instead of simply strongly universal.

Korec [7] also gives a number of other definitions of universality. If the equation $\phi_x(y) = \Phi_M^2(g(x), y)$ in Definition 4 above is replaced with any one of the equations $\phi_x(y) = \Phi_M^1(g_2(x, y))$, $\phi_x(y) = f(\Phi_M^2(g(x), y))$ or $\phi_x(y) = f(\Phi_M^1(g_2(x, y)))$ then the counter machine M is weakly universal. Korec gives another definition where the equation $\phi_x(y) = \Phi_M^2(g(x), y)$ in Definition 4 is replaced with the equation $\phi_x(y) = f(\Phi_M^2(g(x), h(y)))$. However, he does not include this definition in his list of weakly universal machines even though the equation $\phi_x(y) = f(\Phi_M^2(g(x), h(y)))$ allows for a more relaxed encoding than the equation $\phi_x(y) = f(\Phi_M^2(g(x), y))$ and thus gives a weaker form of universality.

For each number $m > 2$ there exists universal m -counter machines that allow ϕ_x^n and its input $(y_1, y_2, \dots, y_n)$ to be encoded separately (e.g. via $g(x)$ and $h^n(y_1, y_2, \dots, y_n)$). For universal 2-counter machines all of the current algorithms encode the function ϕ_x^n and its input $(y_1, y_2, \dots, y_n)$ together as a single input (e.g. via $g^{n+1}(x, y_1, y_2, \dots, y_n)$). Using such encodings it is only possible to give universal 2-counter machines that Korec would class as weakly universal. Some other limitations of 2-counter machines were shown independently by Schroeppe [16] and Barzdin [1]. In both cases the authors are examining unary functions that are uncomputable for 2-counter machines when the input value to the counter machine must equal the input to the function. For example Schroeppe shows that given n as input a 2-counter machine cannot compute 2^n . It is interesting to note that one can give a Korec-strong universal counter machine that is as time/space inefficient as a Korec-weak universal 2-counter machine. Korec's definition of strong universality deals with input and output only and is not concerned with the (time/space) efficiency of the computation.

In earlier work [15], Korec's notion of strong universality was adopted for SN P systems² as follows: A spiking neural P system Π is strongly universal if $\Pi(10^{y-1}10^{x-1}1) = \phi_x(y)$ for all x and y (here if $\phi_x(y)$ is undefined so to is $\Pi(10^{y-1}10^{x-1}1)$). As with the SN P systems given in [15,18], the systems we give in Theorems 1 and 3 satisfy the notion of strong universality adopted from Korec in [15]. Analogously, our system in Theorem 2 could be compared to what Korec refers to as weak universality. However, as we noted in our analysis above, it could be considered that Korec's notion of strong universality is somewhat arbitrary and we also pointed out some inconsistency in his notion of weak universality. Hence, in this work we rely on time/space complexity analysis to compare the encodings used by small SN P system (see Table 1).

It is well known that counter machines require an exponential time overhead to simulate Turing machines [3]. Counter machines with only 2 counters are universal [10], however, they simulate Turing machines with a double exponential time overhead. In the sequel we give some universal SN P systems that simulate 3-counter machines and others that simulate 2-counter machines. The reason for this is that when using our algorithm there is a trade-off between the size and the time efficiency of the system. This trade-off is dependant on whither we choose to simulate 3-counter machines or 2-counter machines. When simulating Turing machines, 3-counter machines suffer from an exponential time overhead and 2-counter machines suffer from a double-exponential time overhead, and thus the simulation of 3-counter machines is preferable when considering the time efficiency of the system. If we are considering the size of our system then 2-counter machines have an advantage over 3-counter machines as our algorithms require a constant number of neurons to simulate each counter.

4. Small universal SN P systems

We begin this section by giving our two extended universal systems Π_{C_3} and Π_{C_2} , and following this we give our standard system Π'_{C_3} . We prove the universality of Π_{C_3} and Π'_{C_3} by showing that they each simulate a universal 3-counter machine. From Π_{C_3} we obtain the system Π'_{C_2} which simulates a universal 2-counter machine.

Theorem 1 *Let C_3 be a universal counter machine with 3 counters that completes its computation in time t to give the output value x_o when given the pair of input values (x_1, x_2) . Then there is a universal extended SN P system Π_{C_3} that simulates the computation of C_3 in time $O(t+x_1+x_2+x_o)$ and has only 5 neurons.*

PROOF. Let $C_3 = (3, \{c_1, c_2\}, c_2, Q, q_1, q_h)$ where $Q = \{q_1, q_2, \dots, q_h\}$. Our SN P system Π_{C_3} is given by Figure 1 and Table 4. The algorithm given for Π_{C_3} is deterministic.

4.0.1. Encoding of a configuration of C_3 and reading input into Π_{C_3}

A configuration of C_3 is stored as spikes in the neurons of Π_{C_3} . The next instruction q_i to be executed is stored in each of the neurons σ_2, σ_3 and σ_4 as $4(h+i)$ spikes. Let x_1, x_2 and x_3 be the values stored in counters c_1, c_2 and c_3 , respectively. Then the values x_1, x_2 and x_3 are stored as $8h(x_1+1)$, $8h(x_2+1)$ and $8h(x_3+1)$ spikes in neurons σ_2, σ_3 and σ_4 , respectively.

The input to Π_{C_3} is read into the system via the input neuron σ_1 (see Figure 1). If C_3 begins its computation with the values x_1 and x_2 in counters c_1 and c_2 , respectively, then the binary sequence $w = 10^{x_1-1}10^{x_2-1}1$ is read in via the input neuron σ_1 . Thus, σ_1 receives a single spike from the

² Note that no formal definition of this notion was explicitly given in [15].

Fig. 1. Universal extended SN P system Π_{C_3} . Each oval labeled σ_i is a neuron. An arrow going from neuron σ_i to neuron σ_j illustrates a synapse (i, j) .

environment at times t_1 , t_{x_1+1} and $t_{x_1+x_2+1}$. We explain how the system is initialised to encode an initial configuration of C_3 by giving the number of spikes in each neuron and the rule that is to be applied in each neuron at time t . Before the computation begins neuron σ_1 initially contain $8h$ spikes, σ_3 contains 2 spikes, σ_4 contains $8h + 1$ spikes and all other neurons contain no spikes. Thus, when σ_1 receives it first spike at time t_1 we have

$$\begin{array}{ll}
 t_1 : & \\
 \sigma_1 = 8h + 1, & s^{8h+1}/s^{8h} \rightarrow s^{8h}, \\
 \sigma_3 = 2, & s^2/s \rightarrow s, \\
 \sigma_4 = 8h + 1, & s^{8h+1}/s^{8h} \rightarrow s^{8h-1}.
 \end{array}$$

where on the left $\sigma_k = z$ gives the number z of spikes in neuron σ_k at time t and on the right is the rule that is to be applied at time t , if there is an applicable rule at that time. Thus, from Figure 1, when we apply the rule $s^{8h+1}/s^{8h} \rightarrow s^{8h}$ in neuron σ_1 , $s^2/s \rightarrow s$ in σ_3 , and $s^{8h+1}/s^{8h} \rightarrow s^{8h-1}$ in σ_4 at time t_1 we get

$$\begin{array}{ll}
 t_2 : & \\
 \sigma_1 = 8h + 1, & s^{8h+1}/s^{8h} \rightarrow s^{8h}, \\
 \sigma_2 = 8h, & \\
 \sigma_3 = 8h + 1, & s^{8h+1}/s^{8h} \rightarrow s, \\
 \sigma_4 = 8h + 1, & s^{8h+1}/s^{8h} \rightarrow s^{8h-1}, \\
 \sigma_5 = 1, & s \rightarrow \lambda,
 \end{array}$$

$$\begin{array}{ll}
 t_3 : & \\
 \sigma_1 = 8h + 1, & s^{8h+1}/s^{8h} \rightarrow s^{8h}, \\
 \sigma_2 = 16h, & \\
 \sigma_3 = 8h + 1, & s^{8h+1}/s^{8h} \rightarrow s, \\
 \sigma_4 = 8h + 1, & s^{8h+1}/s^{8h} \rightarrow s^{8h-1}, \\
 \sigma_5 = 1, & s \rightarrow \lambda.
 \end{array}$$

Neuron σ_1 fires on every timestep between times t_1 and t_{x_1+1} to send a total of $8hx_1$ spikes to σ_2 thus we get

$$\begin{array}{ll}
t_{x_1+1} : & \\
\sigma_1 = 8h + 2, & s^{8h+2}/s^{8h+1} \rightarrow s^{8h+1}, \\
\sigma_2 = 8hx_1, & \\
\sigma_3 = 8h + 1, & s^{8h+1}/s^{8h} \rightarrow s, \\
\sigma_4 = 8h + 1, & s^{8h+1}/s^{8h} \rightarrow s^{8h-1}, \\
\sigma_5 = 1, & s \rightarrow \lambda,
\end{array}$$

$$\begin{array}{ll}
t_{x_1+2} : & \\
\sigma_1 = 8h + 1, & s^{8h+1}/s^{8h} \rightarrow s^{8h}, \\
\sigma_2 = 8h(x_1 + 1) + 1, & (s^{8h})^* s^{8h+1}/s^{8h} \rightarrow s, \\
\sigma_3 = 8h + 2, & \\
\sigma_4 = 8h + 2, & s^{8h+2}/s^{8h} \rightarrow s^{8h-1}, \\
\sigma_5 = 1, & s \rightarrow \lambda,
\end{array}$$

$$\begin{array}{ll}
t_{x_1+3} : & \\
\sigma_1 = 8h + 1, & s^{8h+1}/s^{8h} \rightarrow s^{8h}, \\
\sigma_2 = 8h(x_1 + 1) + 1, & (s^{8h})^* s^{8h+1}/s^{8h} \rightarrow s, \\
\sigma_3 = 16h + 2, & \\
\sigma_4 = 8h + 2, & s^{8h+2}/s^{8h} \rightarrow s^{8h-1}.
\end{array}$$

Neuron σ_1 fires on every timestep between times t_{x_1+1} and $t_{x_1+x_2+1}$ to send a total of $8hx_2$ spikes to σ_3 . Thus, when σ_1 receives the last spike from its environment we have

$$\begin{array}{ll}
t_{x_1+x_2+1} : & \\
\sigma_1 = 8h + 2, & s^{8h+2}/s^{8h+1} \rightarrow s^{8h+1}, \\
\sigma_2 = 8h(x_1 + 1) + 1, & (s^{8h})^* s^{8h+1}/s^{8h} \rightarrow s, \\
\sigma_3 = 8hx_2 + 2, & \\
\sigma_4 = 8h + 2, & s^{8h+2}/s^{8h} \rightarrow s^{8h-1}
\end{array}$$

$$\begin{array}{ll}
t_{x_1+x_2+2} : & \\
\sigma_1 = 8h + 1, & s^{8h+1}/s^{8h} \rightarrow s^{8h}, \\
\sigma_2 = 8h(x_1 + 1) + 2, & (s^{8h})^* s^{8h+2}/s^{8h+2} \rightarrow s^{2h}, \\
\sigma_3 = 8h(x_2 + 1) + 3, & (s^{8h})^* s^{8h+3}/s^{8h+3} \rightarrow s^{2h}, \\
\sigma_4 = 8h + 3, & s^{8h+3} \rightarrow s^{2h}.
\end{array}$$

$$\begin{aligned}
t_{x_1+x_2+3} : \\
\sigma_1 &= 6h + 1, & s^{6h+1} &\rightarrow s^{4h+4}, \\
\sigma_2 &= 8h(x_1 + 1), \\
\sigma_3 &= 8h(x_2 + 1), \\
\sigma_4 &= 8h, \\
\sigma_5 &= 2h, & s^{2h} &\rightarrow \lambda,
\end{aligned}$$

$$\begin{aligned}
t_{x_1+x_2+4} : \\
\sigma_2 &= 8h(x_1 + 1) + 4(h + 1), \\
\sigma_3 &= 8h(x_2 + 1) + 4(h + 1), \\
\sigma_4 &= 8h + 4(h + 1).
\end{aligned}$$

At time $t_{x_1+x_2+4}$ neuron σ_2 contains $8h(x_1 + 1) + 4(h + 1)$ spikes, σ_3 contains $8h(x_2 + 1) + 4(h + 1)$ spikes and σ_4 contains $8h + 4(h + 1)$ spikes. Thus at time $t_{x_1+x_2+4}$ the SN P system encodes an initial configuration of C_3 .

4.0.2. Π_{C_3} simulating $q_i : INC(1), q_l$

Let counters c_1 , c_2 , and c_3 have values x_1 , x_2 , and x_3 , respectively. Then the simulation of $q_i : INC(1), q_l$ begins at time t_j with $8h(x_1 + 1) + 4(h + i)$ spikes in σ_2 , $8h(x_2 + 1) + 4(h + i)$ spikes in σ_3 and $8h(x_3 + 1) + 4(h + i)$ spikes in σ_4 . Thus, at time t_j we have

$$\begin{aligned}
t_j : \\
\sigma_2 &= 8h(x_1 + 1) + 4(h + i), & (s^{8h})^* s^{4(h+i)} / s^{4(h+i)} &\rightarrow s^{4(h+i)}, \\
\sigma_3 &= 8h(x_2 + 1) + 4(h + i), & (s^{8h})^* s^{4(h+i)} / s^{8h+4(h+i)} &\rightarrow s^{6h}, \\
\sigma_4 &= 8h(x_3 + 1) + 4(h + i), & (s^{8h})^* s^{4(h+i)} / s^{8h+4(h+i)} &\rightarrow s^{6h}.
\end{aligned}$$

From Figure 1, when we apply the rule $(s^{8h})^* s^{4(h+i)} / s^{4(h+i)} \rightarrow s^{4(h+i)}$ in neuron σ_2 and the rule $(s^{8h})^* s^{4(h+i)} / s^{8h+4(h+i)} \rightarrow s^{6h}$ in σ_3 and σ_4 at time t_j we get

$$\begin{aligned}
t_{j+1} : \\
\sigma_1 &= 16h + 4i, & s^{16h+4i} &\rightarrow s^{12h+4l}, \\
\sigma_2 &= 8h(x_1 + 1), \\
\sigma_3 &= 8hx_2, \\
\sigma_4 &= 8hx_3, \\
\sigma_5 &= 6h, & s^{6h} &\rightarrow \lambda,
\end{aligned}$$

$$\begin{aligned}
t_{j+2} : \\
\sigma_2 &= 8h(x_1 + 2) + 4(h + l), \\
\sigma_3 &= 8h(x_2 + 1) + 4(h + l), \\
\sigma_4 &= 8h(x_3 + 1) + 4(h + l),
\end{aligned}$$

At time t_{j+2} the simulation of $q_i : INC(1), q_l$ is complete. Note that an increment on the value x_1 in counter c_1 was simulated by increasing the $8h(x_1 + 1)$ spikes in σ_2 to $8h(x_1 + 2)$ spikes. Note also that the encoding $4(h + l)$ of the next instruction q_l has been established in neurons σ_2 , σ_3 and σ_4 .

4.0.3. Π_{C_3} simulating $q_i : DEC(1), q_l, q_k$

There are two cases to consider here. Case 1: if counter c_1 has value $x_1 > 0$, then decrement counter 1 and move to instruction q_{i+1} . Case 2: if counter c_1 has value $x_1 = 0$, then move to instruction q_k . As with the previous example, our simulation begins at time t_j . Thus Case 1 ($x_1 > 0$) gives

$$\begin{aligned}
 t_j : \\
 \sigma_2 &= 8h(x_1 + 1) + 4(h + i), & (s^{8h})^* s^{16h+4(h+i)} / s^{12h+4i} &\rightarrow s^{6h+4i}, \\
 \sigma_3 &= 8h(x_2 + 1) + 4(h + i), & (s^{8h})^* s^{4(h+i)} / s^{4(h+i)} &\rightarrow s^{2h}, \\
 \sigma_4 &= 8h(x_3 + 1) + 4(h + i), & (s^{8h})^* s^{4(h+i)} / s^{4(h+i)} &\rightarrow s^{2h},
 \end{aligned}$$

$$\begin{aligned}
 t_{j+1} : \\
 \sigma_1 &= 10h + 4i, & s^{10h+4i} &\rightarrow s^{4(h+l)}, \\
 \sigma_2 &= 8hx_1, \\
 \sigma_3 &= 8h(x_2 + 1), \\
 \sigma_4 &= 8h(x_3 + 1), \\
 \sigma_5 &= 2h, & s^{2h} &\rightarrow \lambda,
 \end{aligned}$$

$$\begin{aligned}
 t_{j+2} : \\
 \sigma_2 &= 8hx_1 + 4(h + l), \\
 \sigma_3 &= 8h(x_2 + 1) + 4(h + l), \\
 \sigma_4 &= 8h(x_3 + 1) + 4(h + l).
 \end{aligned}$$

At time t_{j+2} the simulation of $q_i : DEC(1), q_l, q_k$ for Case 1 ($x_1 > 0$) is complete. Note that a decrement on the value x_1 in counter c_1 was simulated by decreasing the $8h(x_1 + 1)$ spikes in σ_2 to $8hx_1$ spikes. Note also that the encoding $4(h + l)$ of the next instruction q_l has been established in neurons σ_2 , σ_3 and σ_4 . Alternatively, if we have Case 2 ($x_1 = 0$) then we get

$$\begin{aligned}
 t_j : \\
 \sigma_2 &= 8h + 4(h + i), & s^{8h+4(h+i)} / s^{4(h+i)} &\rightarrow s^{4(h+i)}, \\
 \sigma_3 &= 8h(x_2 + 1) + 4(h + i), & (s^{8h})^* s^{4(h+i)} / s^{4(h+i)} &\rightarrow s^{2h}, \\
 \sigma_4 &= 8h(x_3 + 1) + 4(h + i), & (s^{8h})^* s^{4(h+i)} / s^{4(h+i)} &\rightarrow s^{2h},
 \end{aligned}$$

$$\begin{aligned}
 t_{j+1} : \\
 \sigma_1 &= 8h + 4i, & s^{8h+4i} &\rightarrow s^{4(h+k)}, \\
 \sigma_2 &= 8h, \\
 \sigma_3 &= 8h(x_2 + 1), \\
 \sigma_4 &= 8h(x_3 + 1), \\
 \sigma_5 &= 2h, & s^{2h} &\rightarrow \lambda.
 \end{aligned}$$

$$\begin{aligned}
t_{j+2} : \\
\sigma_2 &= 8h + 4(h + k), \\
\sigma_3 &= 8h(x_2 + 1) + 4(h + k), \\
\sigma_4 &= 8h(x_3 + 1) + 4(h + k).
\end{aligned}$$

At time t_{j+2} the simulation of $q_i : DEC(1), q_l, q_k$ for Case 1 ($x_1 = 0$) is complete. The encoding $4(h + k)$ of the next instruction q_k has been established in neurons σ_2, σ_3 and σ_4 .

4.0.4. Halting

The halt instruction q_h is encoded as $4h + 5$ spikes. Thus, if C_3 enters the halt instruction q_h we get

$$\begin{aligned}
t_j : \\
\sigma_2 &= 8h(x_1 + 1) + 4h + 5, \\
\sigma_3 &= 8h(x_o + 1) + 4h + 5, \\
\sigma_4 &= 8h(x_3 + 1) + 4h + 5,
\end{aligned}
\quad (s^{8h})^* s^{20h+5} / s^{12h} \rightarrow s^2,$$

$$\begin{aligned}
t_{j+1} : \\
\sigma_1 &= 2, & s^2 &\rightarrow \lambda, \\
\sigma_2 &= 8h(x_1 + 1) + 4h + 5, \\
\sigma_3 &= 8hx_o + 5, & (s^{8h})^* s^{16h+5} / s^{8h} &\rightarrow s, \\
\sigma_4 &= 8h(x_3 + 1) + 4h + 5, \\
\sigma_5 &= 2, & s^2 &\rightarrow s,
\end{aligned}$$

$$\begin{aligned}
t_{j+2} : \\
\sigma_1 &= 1, & s &\rightarrow \lambda, \\
\sigma_2 &= 8h(x_1 + 1) + 4h + 5, \\
\sigma_3 &= 8h(x_o - 1) + 5, & (s^{8h})^* s^{16h+5} / s^{8h} &\rightarrow s, \\
\sigma_4 &= 8h(x_3 + 1) + 4h + 5, \\
\sigma_5 &= 1, & s &\rightarrow \lambda.
\end{aligned}$$

The rule $(s^{8h})^* s^{16h+5} / s^{8h} \rightarrow s$ is applied a further $x_o - 2$ times in σ_3 until we get

$$\begin{aligned}
t_{j+x_o} : \\
\sigma_1 &= 1, & s &\rightarrow \lambda, \\
\sigma_2 &= 8h(x_1 + 1) + 4h + 5, \\
\sigma_3 &= 8h + 5, & s^{8h+5} &\rightarrow s^2, \\
\sigma_4 &= 8h(x_3 + 1) + 4h + 5, \\
\sigma_5 &= 1, & s &\rightarrow \lambda.
\end{aligned}$$

$$\begin{array}{ll}
t_{j+x_o+1} : & \\
\sigma_1 = 2, & s^2 \rightarrow \lambda, \\
\sigma_2 = 8h(x_1 + 1) + 4h + 5, & \\
\sigma_4 = 8h(x_3 + 1) + 4h + 5, & \\
\sigma_5 = 2, & s^2 \rightarrow s.
\end{array}$$

As usual the output is the time interval between the first and second spikes that are sent out of the output neuron. Note from above that the output neuron σ_5 fires for the first time at timestep t_{j+1} and for the second time at timestep t_{j+x_o+1} . Thus, the output of Π_{C_3} is x_o the value of the output counter c_2 when C_3 enters the halt instruction q_h . Note that if $x_2 = 0$ then the rule $s^{12h+5} \rightarrow s^2$ is executed at timestep t_j , and thus only one spike will be sent out of the output neuron.

We have now shown how to simulate arbitrary instructions of the form $q_i : INC(1), q_l$ and $q_i : DEC(1), q_l, q_k$ that operate on counter c_1 . Instructions which operate on counters c_2 and c_3 are simulated in a similar manner. Immediately following the simulation of an instruction Π_{C_3} is configured to simulate the next instruction. Each instruction of C_3 is simulated in 2 timesteps. The pair of input values (x_1, x_2) is read into the system in $x_1 + x_2 + 4$ timesteps and sending the output value x_o out of the system takes $x_o + 1$ timesteps. Thus, if C_3 completes its computation in time t , then Π_{C_3} simulates the computation of C_3 in linear time $O(t + x_1 + x_2 + x_o)$. $\square$

Theorem 2 *Let C_2 be a universal counter machine with 2 counters that completes its computation in time t to give the output value x_o when given the input value x_1 . Then there is a universal extended SN P system Π_{C_2} that simulates the computation of C_2 in time $O(t + x_1 + x_o)$ and has only 4 neurons.*

PROOF. Let $C_2 = (2, \{c_1\}, c_2, Q, q_1, q_h)$ where $Q = \{q_1, q_2, \dots, q_h\}$. The rules for the SN P system Π_{C_2} are given by Table 5 and a diagram of the system is obtained by removing neuron σ_4 from Figure 1. If C_2 begins its computation with the value x_1 in counter c_1 then the binary sequence $w = 10^{x_1-1}1$ is read in via the input neuron σ_1 . Before the computation begins neurons $\sigma_1, \sigma_2, \sigma_3$ and σ_5 respectively contain $8h, 8h + 1, 16h + 1$ and 0 spikes. Like Π_{C_3} , Π_{C_2} encodes the value x of each counter as $8h(x + 1)$ spikes and encodes each instruction q_i as $4(h + i)$ spikes. The operation of Π_{C_2} is very similar to the operation of Π_{C_3} , and thus it would be tedious and repetitive to go through another simulation here. Π_{C_2} simulates a single instruction of C_2 in 2 timesteps in a manner similar to that of Π_{C_3} . The inputting and outputting techniques, used by Π_{C_2} , also remain similar to those of Π_{C_3} , and thus the running time of Π_{C_2} is $O(t + x_1 + x_o)$. $\square$

The SN P system in Theorem 3 simulates a counter machine with the following restriction: if a counter is being decremented no other counter has value 0 at that timestep. Note that this does not result in a loss of generality as for each standard counter machine there is a counter machine with this restriction that simulates it in linear time without an increase in the number of counters. Let C be any counter machine with m counters. Then there is a counter machine C' with m counters that simulates C in linear time, such that if C' is decrementing a counter no other counter has value 0 at that timestep. Each counter in C that has value y is simulated by a counter in C' that has value $y + 1$. The instruction set of C' is the same as the instruction set of C with the following exception each $q_i : DEC(j), q_l, q_k$ instruction in C is replaced with the instructions $(q_i : DEC(j)q'_i, q'_i), (q'_i : DEC(j)q_l^*, q_k^*), (q_l^* : INC(j), q_l)$, and $(q_k^* : INC(j), q_k)$. The reason we

Fig. 2. Part 1 of the universal SN P system Π'_{C_3} . Each oval labeled σ_i is a neuron. An arrow going from neuron σ_i to neuron σ_j illustrates a synapse (i, j) .

need these extra instructions is that y is encoded as $y + 1$ and we must decrement twice if we wish to test for an encoded 0.

Theorem 3 *Let C_3 be a universal counter machine with 3 counters and h instructions that completes its computation in time t to give the output value x_o when given the input (x_1, x_2) . Then there is a universal SN P system Π'_{C_3} that simulates the computation of C_3 in time $O(ht + x_1 + x_2 + x_o)$ and has only 17 neurons.*

PROOF. Let $C_3 = (3, \{c_1, c_2\}, c_3, Q, q_1, q_h)$ where $Q = \{q_1, q_2, \dots, q_h\}$. Also, without loss of generality we assume that during C_3 's computation if C_3 is decrementing a counter no other counter has value 0 at that timestep (see the paragraph before Theorem 3). The SN P system Π'_{C_3} is given by Figures 2 and 3 and Tables 6 and 7. As a complement to the figures, Table 3 may be used to identify all the synapses in Π'_{C_3} . The algorithm given for Π'_{C_3} is deterministic.

4.0.5. Encoding of a configuration of C_3 and reading input into Π'_{C_3}

A configuration of C_3 is stored as spikes in the neurons of Π'_{C_3} . The next instruction q_i to be executed is stored in each of the neurons $\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$, and σ_7 as $21(h + i) + 1$ spikes. Let x_1, x_2 and x_3 be the values stored in counters c_1, c_2 and c_3 , respectively. Then the value x_1 is stored as $6(x_1 + 1)$ spikes in neuron σ_8 , x_2 is stored as $6(x_2 + 1)$ spikes in σ_9 , and x_3 is stored as $6(x_3 + 1)$ spikes in σ_{10} .

The input to Π'_{C_3} is read into the system via the input neuron σ_1 (see Figure 2). If C_3 begins its computation with the values x_1 and x_2 in counters c_1 and c_2 , respectively, then the binary sequence $w = 10^{x_1-1}10^{x_2-1}1$ is read in via the input neuron σ_1 . Thus, σ_1 receives a spike from the environment at times t_1 , t_{x_1+1} and $t_{x_1+x_2+1}$. We explain how the system is initialised to encode an initial configuration of C_3 by giving the number of spikes in each neuron and the rule that is to be applied in each neuron at time t . Before the computation begins neurons $\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$ and σ_7 each contain 40 spikes, neurons σ_8, σ_9 and σ_{10} each contain 3 spikes, and neurons σ_{12}, σ_{13} and σ_{14} each contain $21h - 2$ spikes. Thus, when σ_1 receives its first spike at time t_1 we have

$$\begin{aligned}
t_1 : \\
& \sigma_1 = 1, & s \rightarrow s, \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 40, \\
& \sigma_8, \sigma_9, \sigma_{10} = 3, \\
& \sigma_{12}, \sigma_{13}, \sigma_{14} = 21h - 2, & (s^3)^* s^4 / s^3 \rightarrow s.
\end{aligned}$$

Thus, from Figures 2 and 3, when we apply the rule $s \rightarrow s$ in neuron σ_1 and the rule $(s^3)^* s^4 / s^3 \rightarrow s$ in σ_{12}, σ_{13} and σ_{14} at time t_1 we get

$$\begin{aligned}
t_2 : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 41, & s^{41} / s \rightarrow s, \\
& \sigma_8, \sigma_9, \sigma_{10} = 4, \\
& \sigma_{12}, \sigma_{13}, \sigma_{14} = 21h - 4, \\
& \sigma_{15}, \sigma_{16}, \sigma_{17} = 3, \\
\\
t_3 : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 41, & s^{41} / s \rightarrow s, \\
& \sigma_8 = 10, \\
& \sigma_9, \sigma_{10} = 10, & (s^6)^* s^{10} / s^6 \rightarrow s, \\
& \sigma_{11} = 6, & s^6 \rightarrow \lambda, \\
& \sigma_{12}, \sigma_{13}, \sigma_{14} = 21h - 4, \\
& \sigma_{15}, \sigma_{16}, \sigma_{17} = 3.
\end{aligned}$$

$$\begin{aligned}
t_4 : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 43, & s^{43} / s^3 \rightarrow s, \\
& \sigma_8 = 16, \\
& \sigma_9, \sigma_{10} = 10, & (s^6)^* s^{10} / s^6 \rightarrow s, \\
& \sigma_{11} = 7, & s^7 \rightarrow \lambda, \\
& \sigma_{12}, \sigma_{13}, \sigma_{14} = 21h - 4, \\
& \sigma_{15}, \sigma_{16}, \sigma_{17} = 3.
\end{aligned}$$

Neurons $\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$ and σ_7 fire on every timestep between times t_2 and t_{x_1+2} to send a total of $6x_1$ spikes to σ_8 , and thus we get

$t_{x_1+1} :$

$$\begin{aligned}
\sigma_1 &= 1, & s &\rightarrow s, \\
\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 43, & s^{43}/s^3 &\rightarrow s, \\
\sigma_8 &= 6(x_1 - 1) + 4, \\
\sigma_9, \sigma_{10} &= 10, & (s^6)^* s^{10}/s^6 &\rightarrow s, \\
\sigma_{11} &= 7, & s^7 &\rightarrow \lambda, \\
\sigma_{12}, \sigma_{13}, \sigma_{14} &= 21h - 4, \\
\sigma_{15}, \sigma_{16}, \sigma_{17} &= 3,
\end{aligned}$$

$t_{x_1+2} :$

$$\begin{aligned}
\sigma_2 &= 44, & s^{44}/s^{25} &\rightarrow s, \\
\sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 44, & s^{44}/s^{31} &\rightarrow s, \\
\sigma_8 &= 6x_1 + 5, & (s^6)^* s^{11}/s^6 &\rightarrow s, \\
\sigma_9 &= 11, \\
\sigma_{10} &= 11, & (s^6)^* s^{11}/s^6 &\rightarrow s, \\
\sigma_{11} &= 7, & s^7 &\rightarrow \lambda, \\
\sigma_{12}, \sigma_{13}, \sigma_{14} &= 21h - 3, \\
\sigma_{15}, \sigma_{16}, \sigma_{17} &= 3,
\end{aligned}$$

$t_{x_1+3} :$

$$\begin{aligned}
\sigma_2 &= 22, & s^{22}/s^3 &\rightarrow s, \\
\sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 16, & s^{16}/s^3 &\rightarrow s, \\
\sigma_8 &= 6x_1 + 5, & (s^6)^* s^{11}/s^6 &\rightarrow s, \\
\sigma_9 &= 17, \\
\sigma_{10} &= 11, & (s^6)^* s^{11}/s^6 &\rightarrow s, \\
\sigma_{11} &= 7, & s^7 &\rightarrow \lambda, \\
\sigma_{12}, \sigma_{13}, \sigma_{14} &= 21h - 3, \\
\sigma_{15}, \sigma_{16}, \sigma_{17} &= 3.
\end{aligned}$$

Neurons $\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$ and σ_7 fire on every timestep between times t_{x_1+2} and $t_{x_1+x_2+2}$ to send a total of $6x_2$ spikes to σ_9 . Thus, when σ_1 receives the last spike from its environment we have

$t_{x_1+x_2+1} :$

$$\begin{aligned}
\sigma_1 &= 1, & s &\rightarrow s, \\
\sigma_2 &= 22, & s^{22}/s^3 &\rightarrow s, \\
\sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 16, & s^{16}/s^3 &\rightarrow s, \\
\sigma_8 &= 6x_1 + 5, & (s^6)^* s^{11}/s^6 &\rightarrow s, \\
\sigma_9 &= 6x_2 + 5, & & \\
\sigma_{10} &= 11, & (s^6)^* s^{11}/s^6 &\rightarrow s, \\
\sigma_{11} &= 7, & s^7 &\rightarrow \lambda, \\
\sigma_{12}, \sigma_{13}, \sigma_{14} &= 21h - 3, & & \\
\sigma_{15}, \sigma_{16}, \sigma_{17} &= 3, & &
\end{aligned}$$

$t_{x_1+x_2+2} :$

$$\begin{aligned}
\sigma_2 &= 23, & s^{23}/s^5 &\rightarrow s, \\
\sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 17, & & \\
\sigma_8 &= 6(x_1 + 1), & & \\
\sigma_9 &= 6(x_2 + 2), & & \\
\sigma_{10} &= 12, & & \\
\sigma_{11} &= 7, & s^7 &\rightarrow \lambda, \\
\sigma_{12}, \sigma_{13}, \sigma_{14} &= 21h - 2, & (s^3)^* s^4/s^3 &\rightarrow s, \\
\sigma_{15}, \sigma_{16}, \sigma_{17} &= 3, & &
\end{aligned}$$

$t_{x_1+x_2+3} :$

$$\begin{aligned}
\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 18, & & \\
\sigma_8 &= 6(x_1 + 1) + 1, & (s^6)^* s^{13}/s &\rightarrow s, \\
\sigma_9 &= 6(x_2 + 2) + 1, & (s^6)^* s^7/s^7 &\rightarrow s, \\
\sigma_{10} &= 13, & (s^6)^* s^7/s^7 &\rightarrow s, \\
\sigma_{11} &= 1, & s &\rightarrow \lambda, \\
\sigma_{12}, \sigma_{13}, \sigma_{14} &= 21h - 5, & (s^3)^* s^4/s^3 &\rightarrow s, \\
\sigma_{15}, \sigma_{16}, \sigma_{17} &= 6, & &
\end{aligned}$$

$t_{x_1+x_2+4} :$

$$\begin{aligned}
\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 21, & & \\
\sigma_8 &= 6(x_1 + 1), & & \\
\sigma_9 &= 6(x_2 + 1), & & \\
\sigma_{10} &= 6, & & \\
\sigma_{11} &= 1, & s &\rightarrow \lambda, \\
\sigma_{12}, \sigma_{13}, \sigma_{14} &= 21h - 8, & (s^3)^* s^4/s^3 &\rightarrow s, \\
\sigma_{15}, \sigma_{16}, \sigma_{17} &= 9. & &
\end{aligned}$$

After a further $7h - 3$ timestep we get

$$\begin{aligned}
& t_{x_1+x_2+7h+1} : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21, \\
& \sigma_8 = 6(x_1 + 1), \\
& \sigma_9 = 6(x_2 + 1), \\
& \sigma_{10} = 6, \\
& \sigma_{12} = 1, & s \rightarrow s, \\
& \sigma_{13}, \sigma_{14} = 1, & s \rightarrow \lambda, \\
& \sigma_{15}, \sigma_{16}, \sigma_{17} = 21h,
\end{aligned}$$

$$\begin{aligned}
& t_{x_1+x_2+7h+2} : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21, \\
& \sigma_8 = 6(x_1 + 1), \\
& \sigma_9 = 6(x_2 + 1), \\
& \sigma_{10} = 6, \\
& \sigma_{15}, \sigma_{16}, \sigma_{17} = 21h + 1, & (s^3)^* s^4 / s^3 \rightarrow s,
\end{aligned}$$

$$\begin{aligned}
& t_{x_1+x_2+7h+3} : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21 + 3, \\
& \sigma_8 = 6(x_1 + 1), \\
& \sigma_9 = 6(x_2 + 1), \\
& \sigma_{10} = 6, \\
& \sigma_{12}, \sigma_{13}, \sigma_{14} = 3, \\
& \sigma_{15}, \sigma_{16}, \sigma_{17} = 21h - 2, & (s^3)^* s^4 / s^3 \rightarrow s.
\end{aligned}$$

Neurons σ_{15} , σ_{16} and σ_{17} continue to fire at each timestep. Thus, after a further $7h - 1$ steps we get

$$\begin{aligned}
& t_{x_1+x_2+14h+2} : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21h + 21, \\
& \sigma_8 = 6(x_1 + 1), \\
& \sigma_9 = 6(x_2 + 1), \\
& \sigma_{10} = 6, \\
& \sigma_{12}, \sigma_{13}, \sigma_{14} = 21h, \\
& \sigma_{15} = 1, & s \rightarrow s, \\
& \sigma_{16}, \sigma_{17} = 1, & s \rightarrow \lambda.
\end{aligned}$$

Fig. 3. Part 2 of the universal SN P system Π'_{C_3} . Each oval labeled σ_i is a neuron. An arrow going from neuron σ_i to neuron σ_j illustrates a synapse (i, j) .

$$\begin{aligned}
 & t_{x_1+x_2+14h+3} : \\
 & \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21(h+1) + 1, \\
 & \sigma_8 = 6(x_1 + 1), \\
 & \sigma_9 = 6(x_2 + 1), \\
 & \sigma_{10} = 6, \\
 & \sigma_{12}, \sigma_{13}, \sigma_{14} = 21h + 1.
 \end{aligned}$$

At time $t_{x_1+x_2+14h+3}$ neurons $\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$ and σ_7 each contain $21(h+1) + 1$ spikes, σ_8 contains $6(x_1 + 1)$ spikes, σ_9 contains $6(x_2 + 1)$ spikes and σ_{10} contains 6 spikes. Thus, at time $t_{x_1+x_2+14h+3}$ the SN P system encodes an initial configuration of C_3 .

4.0.6. Algorithm overview

Here we give a high level overview of the simulation algorithm used by Π'_{C_3} . Neurons σ_8, σ_9 and σ_{10} simulate the counters of c_1, c_2 and c_3 , respectively. Neurons $\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$ and σ_7 are the *control neurons*. They determine which instruction is to be simulated next by sending signals to the neurons that simulate the counters of C_3 directing them to simulate an increment or decrement. There are four different signals that the control neurons send to the simulated counters. Each of these signals takes the form of a unique number of spikes. If 1 spike is sent to σ_8, σ_9 and σ_{10} then the value in σ_8 (counter c_1) is tested and σ_9 (counter c_2) and σ_{10} (counter c_3) are decremented. If 2 spikes are sent the value of σ_9 is tested and σ_8 and σ_{10} are decremented. If 3 spikes are sent the value of σ_{10} is tested and σ_8 and σ_9 are decremented. Finally, if 6 spikes are sent all three counters are incremented. Unfortunately, all of the above signals have the effect of changing the value of more than one simulated counter at a time. We can, however, obtain the desired result by using more than one signal for each simulated timestep. If we wish to simulate *INC* we send 2 signals and if we wish to simulate *DEC* we send either 8 or 2 signals. Table 2 gives the sequence of spikes (signals) to be sent in order to simulate each counter machine instruction. To explain how to use Table 2 we will take the example of simulating *INC*(2). In the first timestep, all three simulated

Instruction	Sequence of spikes sent from $\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$ and σ_7
<i>INC</i> (1)	6, 1
<i>INC</i> (2)	6, 2
<i>INC</i> (3)	6, 3
<i>DEC</i> (1)	1, 0, 6 if $x_1 = 0$
<i>DEC</i> (1)	1, 0, 6, 6, 6, 3, 3, 2 if $x_1 > 0$
<i>DEC</i> (2)	2, 0, 6 if $x_2 = 0$
<i>DEC</i> (2)	2, 0, 6, 6, 6, 3, 3, 1, 1 if $x_2 > 0$
<i>DEC</i> (3)	3, 0, 6 if $x_3 = 0$
<i>DEC</i> (3)	3, 0, 6, 6, 6, 2, 2, 1, 1 if $x_3 > 0$

Table 2

This table gives a counter machine instruction in the left column followed, in the right column, by the sequence that is used by Π'_{C_3} to simulated that instruction. Each number in the sequence represents the total number of spikes to be sent from the set of neurons $\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$ and σ_7 at each timestep.

counters σ_8, σ_9 and σ_{10} are incremented by sending 6 spikes, and then in the second timestep the simulated counters σ_8 and σ_{10} are decremented by sending 2 spikes. This has the effect of simulating an increment in counter c_2 and leaving the other two simulated counters unchanged.

Each counter machine instruction q_i is encoded as $21(h + i) + 1$ spikes in each of the control neurons. At the end of each simulated timestep the number of spikes in the control neurons must be updated to encode the next instruction q_k . The update rule $s^{21(h+i)-21k} \rightarrow s$ is applied in each control neuron leaving a total of $21k$ spikes in each control neuron. Following this, $21h + 1$ spikes are sent from neurons σ_{15}, σ_{16} and σ_{17} to each of the control neurons. This gives a total of $21(h + k) + 1$ spikes in each control neuron. Thus encoding the next instruction q_k . (Note that the rule $s^{21(h+i)-21k} \rightarrow s$ is simplification of the actual rule used.)

4.0.7. Π'_{C_3} simulating $q_i : INC(1), q_l$

The simulation of *INC*(1) is given by the neurons in Figures 2 and 3. Let x_1, x_2 and x_3 be the values in counters c_1, c_2 and c_3 respectively. Then our simulation of $q_i : INC(1), q_l$ begins with $6(x_1 + 1)$ spikes in σ_8 , $6(x_2 + 1)$ spikes in σ_9 , $6(x_3 + 1)$ spikes in σ_{10} , $21(h + i) + 1$ spikes in each of the neurons $\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$ and σ_7 , and $21h + 1$ spikes in each of the neurons σ_{12}, σ_{13} and σ_{14} . Beginning our simulation at time t_j , we have

$t_j :$

$$\begin{aligned}
\sigma_2 &= 21(h + i) + 1, & s^{21(h+i)+1}/s^4 &\rightarrow s, \\
\sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 21(h + i) + 1, & s^{21(h+i)+1}/s^{21(h+i-l)+6} &\rightarrow s, \\
\sigma_8 &= 6(x_1 + 1), \\
\sigma_9 &= 6(x_2 + 1), \\
\sigma_{10} &= 6(x_3 + 1), \\
\sigma_{12}, \sigma_{13}, \sigma_{14} &= 21h + 1, & (s^3)^*s^4/s^3 &\rightarrow s.
\end{aligned}$$

Thus, from Figures 2 and 3 we get

$$\begin{aligned}
t_{j+1} : \\
& \sigma_2 = 21(h+i) - 2, & s^{21(h+i)-2}/s^{21(h+i-l)+1} \rightarrow s, \\
& \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21l - 4, \\
& \sigma_8 = 6(x_1 + 2), \\
& \sigma_9 = 6(x_2 + 2), \\
& \sigma_{10} = 6(x_3 + 2), \\
& \sigma_{11} = 6, & s^6 \rightarrow \lambda, \\
& \sigma_{12}, \sigma_{13}, \sigma_{14} = 21h - 2, & (s^3)^* s^4 / s^3 \rightarrow s, \\
& \sigma_{15}, \sigma_{16}, \sigma_{17} = 3,
\end{aligned}$$

$$\begin{aligned}
t_{j+2} : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21l - 3, \\
& \sigma_8 = 6(x_1 + 2) + 1, & (s^6)^* s^{13} / s \rightarrow s, \\
& \sigma_9 = 6(x_2 + 2) + 1, & (s^6)^* s^7 / s^7 \rightarrow s, \\
& \sigma_{10} = 6(x_3 + 2) + 1, & (s^6)^* s^7 / s^7 \rightarrow s, \\
& \sigma_{11} = 1, & s \rightarrow \lambda, \\
& \sigma_{12}, \sigma_{13}, \sigma_{14} = 21h - 5, & (s^3)^* s^4 / s^3 \rightarrow s, \\
& \sigma_{15}, \sigma_{16}, \sigma_{17} = 6,
\end{aligned}$$

$$\begin{aligned}
t_{j+3} : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21l, \\
& \sigma_8 = 6(x_1 + 2), \\
& \sigma_9 = 6(x_2 + 1), \\
& \sigma_{10} = 6(x_3 + 1), \\
& \sigma_{11} = 1, & s \rightarrow \lambda, \\
& \sigma_{12}, \sigma_{13}, \sigma_{14} = 21h - 8, & (s^3)^* s^4 / s^3 \rightarrow s, \\
& \sigma_{15}, \sigma_{16}, \sigma_{17} = 9.
\end{aligned}$$

The remainder of this simulation is similar to the computation carried out at the end of the initialisation process (see the last paragraph of Section 4.0.6 and timesteps $t_{x_1+x_2+4}$ to $t_{x_1+x_2+14h+3}$ of the Section 4.0.5). Thus, after a further $14h - 1$ timesteps we get

$$\begin{aligned}
t_{j+14h+2} : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21(h+l) + 1, \\
& \sigma_8 = 6(x_1 + 2), \\
& \sigma_9 = 6(x_2 + 1), \\
& \sigma_{10} = 6(x_3 + 1), \\
& \sigma_{12}, \sigma_{13}, \sigma_{14} = 21h + 1, & (s^3)^* s^4 / s^3 \rightarrow s.
\end{aligned}$$

At time $t_{j+14h+2}$ the simulation of $q_i : INC(1), q_l$ is complete. Note that an increment on the value x_1 in counter c_1 is simulated by increasing the number of spikes in σ_8 from $6(x_1 + 1)$ to $6(x_1 + 2)$. Note also that the encoding of the next instruction q_l is given by the $21(h + l) + 1$ spikes in neurons $\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$ and σ_7 .

4.0.8. Π'_{C_3} simulating $q_i : DEC(1), q_l, q_k$

If we are simulating $DEC(1)$ then we get

$$\begin{aligned}
 t_j : \\
 \sigma_2 &= 21(h + i) + 1, & s^{21(h+i)+1}/s^5 &\rightarrow s, \\
 \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 21(h + i) + 1, \\
 \sigma_8 &= 6(x_1 + 1), \\
 \sigma_9 &= 6(x_2 + 1), \\
 \sigma_{10} &= 6(x_3 + 1), \\
 \sigma_{12}, \sigma_{13}, \sigma_{14} &= 21h + 1, & (s^3)^*s^4/s^3 &\rightarrow s.
 \end{aligned}$$

To help simplify configurations we will not include neurons σ_{12}, σ_{13} , and σ_{14} until the end of the example. When simulating $DEC(1)$ there are two cases to consider. Case 1: if counter c_1 has value $x_1 > 0$, then decrement counter 1 and move to instruction q_{i+1} . Case 2: if counter c_1 has value $x_1 = 0$, then move to instruction q_k . In configuration t_{j+1} our system determines if the value x_1 in counter 1 is > 0 by checking if the number of spikes in σ_8 is > 13 . Note that if we have Case 1 then the rule $(s^6)^*s^{13}/s \rightarrow s$ is applied in σ_8 sending an extra spike to neurons $\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$ and σ_7 thus recording that $x_1 > 0$. Case 1 proceeds as follows:

$$\begin{aligned}
 t_{j+1} : \\
 \sigma_2 &= 21(h + i) - 4, \\
 \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 21(h + i) + 2, \\
 \sigma_8 &= 6(x_1 + 1) + 1, & (s^6)^*s^{13}/s &\rightarrow s, \\
 \sigma_9 &= 6(x_2 + 1) + 1, & (s^6)^*s^7/s^7 &\rightarrow s, \\
 \sigma_{10} &= 6(x_3 + 1) + 1, & (s^6)^*s^7/s^7 &\rightarrow s, \\
 \sigma_{11} &= 1, & s &\rightarrow \lambda,
 \end{aligned}$$

$$\begin{aligned}
 t_{j+2} : \\
 \sigma_2 &= 21(h + i) - 1, & s^{21(h+i)-1}/s^5 &\rightarrow s, \\
 \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 21(h + i) + 5, & s^{21(h+i)+5}/s^{11} &\rightarrow s, \\
 \sigma_8 &= 6(x_1 + 1), \\
 \sigma_9 &= 6x_2, \\
 \sigma_{10} &= 6x_3 \\
 \sigma_{11} &= 1, & s &\rightarrow \lambda.
 \end{aligned}$$

The method we use to test the value of σ_8 (simulated counter c_1) has the side-effect of decrementing σ_9 (simulated counter c_2) and σ_{10} (simulated counter c_2). Following this, in order to get the correct values our algorithm takes the following steps: Each of our simulated counters (σ_8, σ_9 and σ_{10}) are

incremented 3 times, and then the simulated counter σ_8 is decremented 4 times, whilst the simulated counters σ_9 and σ_{10} are each decremented twice. Thus, the overall result is that a decrement of c_1 is simulated in σ_8 and the other encoded counter values in σ_9 and σ_{10} remain the same. Continuing with our simulation we get

$$\begin{aligned}
t_{j+3} : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21(h+i) - 5, & s^{21(h+i)-5}/s^3 \rightarrow s, \\
& \sigma_8 = 6(x_1 + 2), \\
& \sigma_9 = 6(x_2 + 1), \\
& \sigma_{10} = 6(x_3 + 1), \\
& \sigma_{11} = 6, & s^6 \rightarrow \lambda,
\end{aligned}$$

$$\begin{aligned}
t_{j+4} : \\
& \sigma_2, \sigma_3, \sigma_4 = 21(h+i) - 7, & s^{21(h+i)-7}/s^2 \rightarrow s, \\
& \sigma_5, \sigma_6, \sigma_7 = 21(h+i) - 7, & s^{21(h+i)-7}/s^{21(h+i-l)+10} \rightarrow s, \\
& \sigma_8 = 6(x_1 + 3), \\
& \sigma_9 = 6(x_2 + 2), \\
& \sigma_{10} = 6(x_3 + 2), \\
& \sigma_{11} = 6, & s^6 \rightarrow \lambda,
\end{aligned}$$

$$\begin{aligned}
t_{j+5} : \\
& \sigma_2, \sigma_3, \sigma_4 = 21(h+i) - 8, & s^{21(h+i)-8}/s^3 \rightarrow s, \\
& \sigma_5, \sigma_6, \sigma_7 = 21l - 16, \\
& \sigma_8 = 6(x_1 + 4), \\
& \sigma_9 = 6(x_2 + 3), \\
& \sigma_{10} = 6(x_3 + 3), \\
& \sigma_{11} = 6, & s^6 \rightarrow \lambda.
\end{aligned}$$

In configurations t_{j+3} , t_{j+4} and t_{j+5} each of the simulated counters σ_8 , σ_9 and σ_{10} are incremented. In configurations t_{j+6} to t_{j+10} the simulated counter σ_8 is decremented 4 times and the simulated counters σ_9 and σ_{10} are each decremented twice.

$$\begin{aligned}
t_{j+6} : \\
& \sigma_2, \sigma_3 = 21(h+i) - 10, & s^{21(h+i)-10}/s^5 \rightarrow s, \\
& \sigma_4 = 21(h+i) - 10, & s^{21(h+i)-10}/s^{21(h+i-l)+5} \rightarrow s, \\
& \sigma_5, \sigma_6, \sigma_7 = 21l - 15, \\
& \sigma_8 = 6(x_1 + 4) + 3, & (s^6)^* s^9/s^9 \rightarrow s, \\
& \sigma_9 = 6(x_2 + 3) + 3, & (s^6)^* s^9/s^9 \rightarrow s, \\
& \sigma_{10} = 6(x_3 + 3) + 3, & (s^6)^* s^{15}/s^3 \rightarrow s, \\
& \sigma_{11} = 3, & s^3 \rightarrow \lambda.
\end{aligned}$$

$t_{j+7} :$

$$\begin{aligned}
\sigma_2, \sigma_3 &= 21(h+i) - 11, & s^{21(h+i)-11}/s^6 &\rightarrow s, \\
\sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 21l - 11, \\
\sigma_8 &= 6(x_1 + 3) + 3, & (s^6)^* s^9/s^9 &\rightarrow s, \\
\sigma_9 &= 6(x_2 + 2) + 3, & (s^6)^* s^9/s^9 &\rightarrow s, \\
\sigma_{10} &= 6(x_3 + 3) + 3, & (s^6)^* s^{15}/s^3 &\rightarrow s, \\
\sigma_{11} &= 4, & s^4 &\rightarrow \lambda,
\end{aligned}$$

$t_{j+8} :$

$$\begin{aligned}
\sigma_2, \sigma_3 &= 21(h+i) - 13, & s^{21(h+i)-13}/s^{21(h+i-l)-6} &\rightarrow s, \\
\sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 21l - 7, \\
\sigma_8 &= 6(x_1 + 2) + 2, & (s^6)^* s^8/s^8 &\rightarrow s, \\
\sigma_9 &= 6(x_2 + 1) + 2, & (s^6)^* s^{14}/s^2 &\rightarrow s, \\
\sigma_{10} &= 6(x_3 + 3) + 2, & (s^6)^* s^8/s^8 &\rightarrow s, \\
\sigma_{11} &= 3, & s^3 &\rightarrow \lambda,
\end{aligned}$$

$t_{j+9} :$

$$\begin{aligned}
\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 21l - 3, \\
\sigma_8 &= 6(x_1 + 1) + 2, & (s^6)^* s^8/s^8 &\rightarrow s, \\
\sigma_9 &= 6(x_2 + 1) + 2, & (s^6)^* s^{14}/s^2 &\rightarrow s, \\
\sigma_{10} &= 6(x_3 + 2) + 2, & (s^6)^* s^8/s^8 &\rightarrow s, \\
\sigma_{11} &= 3, & s^3 &\rightarrow \lambda,
\end{aligned}$$

$t_{j+10} :$

$$\begin{aligned}
\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 &= 21l, \\
\sigma_8 &= 6x_1, \\
\sigma_9 &= 6(x_2 + 1), \\
\sigma_{10} &= 6(x_3 + 1), \\
\sigma_{11} &= 1, & s &\rightarrow \lambda, \\
\sigma_{12}, \sigma_{13}, \sigma_{14} &= 21h - 29, & (s^3)^* s^4/s^3 &\rightarrow s, \\
\sigma_{15}, \sigma_{16}, \sigma_{17} &= 30.
\end{aligned}$$

Note that at time t_{j+8} that rule $(s^6)^* s^{14}/s^2 \rightarrow s$ will always be applicable as here $x_2 > 0$ (see the second line at the start of the proof).

The remainder of this simulation is similar to the computation carried out at the end of the initialisation process (see the last paragraph of Section 4.0.6 and timesteps $t_{x_1+x_2+4}$ to $t_{x_1+x_2+14h+3}$ of the Section 4.0.5). Thus, after a further $14h - 8$ timesteps we get

$$\begin{aligned}
t_{j+14h+2} : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21(h+l) + 1, \\
& \sigma_8 = 6x_1, \\
& \sigma_9 = 6(x_2 + 1), \\
& \sigma_{10} = 6(x_3 + 1), \\
& \sigma_{12}, \sigma_{13}, \sigma_{14} = 21h + 1, \quad (s^3)^* s^4 / s^3 \rightarrow s.
\end{aligned}$$

At timestep $t_{j+14h+2}$ the simulation of $q_i : DEC(1), q_l, q_k$ for Case 1 ($x_1 > 0$) is complete. Note that a decrement on the value x_1 in counter c_1 is simulated by decreasing the value in σ_8 from $6(x_1 + 1)$ to $6x_1$. Note also that the encoding $21(h+l) + 1$ of the next instruction q_l has been established in neurons $\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$ and σ_7 . Alternatively, if we have Case 2 ($x_1 = 0$) then we get

$$\begin{aligned}
t_{j+1} : \\
& \sigma_2 = 21(h+i) - 4, \\
& \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21(h+i) + 2, \\
& \sigma_8 = 7, \quad s^7 \rightarrow \lambda, \\
& \sigma_9 = 6(x_2 + 1) + 1, \quad (s^6)^* s^7 / s^7 \rightarrow s, \\
& \sigma_{10} = 6(x_3 + 1) + 1, \quad (s^6)^* s^7 / s^7 \rightarrow s, \\
& \sigma_{11} = 1, \quad s \rightarrow \lambda,
\end{aligned}$$

$$\begin{aligned}
t_{j+2} : \\
& \sigma_2 = 21(h+i) - 2, \quad s^{21(h+i)-2} / s^{21(h+i-k)-1} \rightarrow s, \\
& \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21(h+i) + 4, \quad s^{21(h+i)+4} / s^{21(h+i-k)+5} \rightarrow s, \\
& \sigma_9 = 6x_2, \\
& \sigma_{10} = 6x_3, \\
& \sigma_{11} = 1, \quad s \rightarrow \lambda,
\end{aligned}$$

$$\begin{aligned}
t_{j+3} : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21k, \\
& \sigma_8 = 6, \\
& \sigma_9 = 6(x_2 + 1), \\
& \sigma_{10} = 6(x_3 + 1), \\
& \sigma_{11} = 6, \quad s^6 \rightarrow \lambda, \\
& \sigma_{12}, \sigma_{13}, \sigma_{14} = 21h - 8, \quad (s^3)^* s^4 / s^3 \rightarrow s, \\
& \sigma_{15}, \sigma_{16}, \sigma_{17} = 9.
\end{aligned}$$

The remainder of this simulation is similar to the computation carried out at the end of the initialisation process (see the last paragraph of Section 4.0.6 and timesteps $t_{x_1+x_2+4}$ to $t_{x_1+x_2+14h+3}$

of the Section 4.0.5). Thus, after a further $14h - 1$ timesteps we get

$$\begin{aligned}
t_{j+14h+2} : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7 = 21(h+k) + 1, \\
& \sigma_9 = 6, \\
& \sigma_9 = 6(x_2 + 1), \\
& \sigma_{10} = 6(x_3 + 1), \\
& \sigma_{12}, \sigma_{13}, \sigma_{14} = 21h + 1.
\end{aligned}$$

At time $t_{j+14h+2}$ the simulation of $q_i : DEC(1), q_l, q_k$ for Case 2 ($x_1 = 0$), is complete. Note that the encoding $21(h+k) + 1$ of the next instruction q_k has been established in neurons $\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$ and σ_7 .

4.0.9. Halting

If C_3 enters the halt instruction q_h at time t_j then we get the following

$$\begin{aligned}
t_j : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5 = 42h + 1, & s^{42h+1}/s \rightarrow s, \\
& \sigma_6, \sigma_7 = 42h + 1, \\
& \sigma_8 = 6(x_1 + 1), \\
& \sigma_9 = 6(x_2 + 1), \\
& \sigma_{10} = 6(x_o + 1),
\end{aligned}$$

$$\begin{aligned}
t_{j+1} : \\
& \sigma_2, \sigma_3, \sigma_4, \sigma_5 = 42h + 1, & s^{42h+1}/s \rightarrow s, \\
& \sigma_6, \sigma_7 = 42h + 2, \\
& \sigma_8 = 6(x_1 + 1) + 4, \\
& \sigma_9 = 6(x_2 + 1) + 4, & (s^6)^* s^{10}/s^6 \rightarrow s, \\
& \sigma_{10} = 6(x_o + 1) + 4, & (s^6)^* s^{10}/s^6 \rightarrow s, \\
& \sigma_{11} = 4, & s^4 \rightarrow \lambda,
\end{aligned}$$

$$\begin{aligned}
t_{j+2} : \\
& \sigma_2, \sigma_3 = 42h + 3, & s^* s^{42h+3}/s \rightarrow s, \\
& \sigma_4, \sigma_5 = 42h + 3, \\
& \sigma_6, \sigma_7 = 42h + 5, \\
& \sigma_8 = 6(x_1 + 2) + 2, & (s^6)^* s^8/s^8 \rightarrow s, \\
& \sigma_9 = 6(x_2 + 1) + 2, & (s^6)^* s^{14}/s^2 \rightarrow s, \\
& \sigma_{10} = 6(x_o + 1) + 2, & (s^6)^* s^8/s^8 \rightarrow s, \\
& \sigma_{11} = 5.
\end{aligned}$$

Note that after time t_{j+2} we can ignore neurons $\sigma_4, \sigma_5, \sigma_6$ and σ_7 as there are no rules applicable in these neurons when the number of spikes is $\geq 43h + 3$. The number of spikes in σ_2 and σ_3 does not

decrease following timestep t_{j+2} , and thus the rule $s^*s^{42h+3}/s \rightarrow s$ is applicable at each subsequent timestep regardless of the operation of neurons σ_8 and σ_9 . Thus, neurons σ_8 and σ_9 may also be ignored as their operation has no effect on the remainder of the simulation. Note that in subsequent configurations we write $\sigma_2, \sigma_3 \geq 42h + 3$ as there are more than $42h + 3$ spikes in each of these neurons. Thus we have

$$\begin{array}{ll}
t_{j+3} : & \\
\sigma_2, \sigma_3 \geq 42h + 3, & s^*s^{42h+3}/s \rightarrow s, \\
\sigma_{10} = 6x_o + 2, & (s^6)^*s^8/s^8 \rightarrow s, \\
\sigma_{11} = 8, &
\end{array}$$

$$\begin{array}{ll}
t_{j+4} : & \\
\sigma_2, \sigma_3 \geq 42h + 3, & s^*s^{42h+3}/s \rightarrow s, \\
\sigma_{10} = 6(x_o - 1) + 2, & (s^6)^*s^8/s^8 \rightarrow s, \\
\sigma_{11} = 11, & s^{11}/s^2 \rightarrow s,
\end{array}$$

$$\begin{array}{ll}
t_{j+5} : & \\
\sigma_2, \sigma_3 \geq 42h + 3, & s^*s^{42h+3}/s \rightarrow s, \\
\sigma_{10} = 6(x_o - 2) + 2, & (s^6)^*s^8/s^8 \rightarrow s, \\
\sigma_{11} = 12. &
\end{array}$$

The rule $(s^6)^*s^8/s^8 \rightarrow s$ is applied in σ_{10} a further $x_o - 2$ times until we get

$$\begin{array}{ll}
t_{j+x_o+3} : & \\
\sigma_2, \sigma_3 \geq 42h + 3, & s^*s^{42h+3}/s \rightarrow s, \\
\sigma_{10} = 2, & s^2 \rightarrow \lambda, \\
\sigma_{11} = 3(x_o - 2) + 12, &
\end{array}$$

$$\begin{array}{ll}
t_{j+x_o+4} : & \\
\sigma_2, \sigma_3 \geq 42h + 3, & s^*s^{42h+3}/s \rightarrow s, \\
\sigma_{10} = 2, & s^2 \rightarrow \lambda, \\
\sigma_{11} = 3(x_o - 2) + 14, & (s^3)^*s^{14}/s \rightarrow s.
\end{array}$$

Recall from Section 2 that the output of an SN P system is the time interval between the first and second spikes that are sent out of the output neuron. Note from above that the output neuron σ_{11} fires for the first time at timestep t_{j+4} and for the second time at timestep t_{j+x_o+4} . Thus, the output of Π'_{C_3} is x_o the contents of the output counter c_3 when C_3 enters the halt instruction q_h . If $x_o = 0$ neuron σ_{11} will fire only once. To see this, note that if $x_o = 0$ then $s^2 \rightarrow \lambda$ will be applied in neuron σ_{10} at time t_{j+3} , and thus σ_{11} will have 10 spikes (instead of 11) at time t_{j+4} and the rule $s^{10} \rightarrow s$ will be applied in σ_{11} ending the computation.

We have shown how to simulate arbitrary instructions of the form $q_i : INC(1), q_l$ and $q_i : DEC(1), q_l, q_k$. Instructions that operate on counters c_2 and c_3 are simulated in a similar manner. Immediately following the simulation of an instruction Π'_{C_3} is configured to begin simulation of the next instruction. Each instruction of C_3 is simulated in $14h + 2$ timesteps. The pair of input values

origin neurons	target neurons
σ_1	$\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7, \sigma_8, \sigma_9, \sigma_{10}, \sigma_{12}, \sigma_{13}, \sigma_{14}$

$\sigma_{12}, \sigma_{13}, \sigma_{14}$	$\sigma_{15}, \sigma_{16}, \sigma_{17}$
$\sigma_{15}, \sigma_{16}, \sigma_{17}$	$\sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7, \sigma_{12}, \sigma_{13}, \sigma_{14}$

Table 3

This table gives the set of synapses of the SN P system Π'_{C_3} . Each origin neuron σ_i and target neuron σ_j that appear on the same row have a synapse going from σ_i to σ_j .

Fig. 4. Finite state machine G decides if there is any rule applicable in a neuron given the number of spikes in the neuron *at a given time* in the computation. Each s represents a spike in the neuron. Machine G' keeps track of the movement of spikes into and out of the neuron and decides whether or not a particular rule is applicable *at each timestep* in the computation. $+s$ represents a single spike entering the neuron and $-s$ represents a single spike exiting the neuron.

(x_1, x_2) is read into the system in $x_1 + x_2 + 14h + 3$ timesteps and sending the output value x_o out of the system takes $x_o + 4$ timesteps. Thus, if C_3 completes its computation in time t then Π'_{C_3} simulates the computation of C_3 in linear time $O(ht + x_1 + x_2 + x_o)$. $\square$

5. Lower bounds for small universal SN P systems

In this section we show that there exists no universal SN P system with only 3 neurons even when we allow the input technique to be generalised. This is achieved in Theorem 4 by showing that these systems are simulated by log-space bounded Turing machines. Following this, we show that if we generalise the output technique we can give a universal SN P system with extended rules that has only 3 neurons. As a corollary of our proof of Theorem 4, we find that a universal SN P system with extended rules and generalised input and output is not possible with 2 neurons.

In this and other work [15,18] on small SN P systems the input neuron only receives a constant number of spikes from the environment and the output neuron fires no more than a constant number of times. Hence, we call input standard if the input neuron receives no more than y spikes from the environment, where y is a constant independent of the input (i.e. the number of 1s in its input sequence is $< y$). Similarly, we call the output standard if the output neuron fires no more than x times, where x is a constant independent of the input. Here we say an SN P system has generalised input if the input neuron is permitted to receive $\leq n$ spikes from the environment where $n \in \mathbb{N}$ is the length of its input sequence.

Theorem 4 *Let Π be any extended SN P system with only 3 neurons, generalised input and standard output. Then there is a non-deterministic Turing machine T_Π that simulates the computation of Π in space $O(\log n)$ where n is the length of the input to Π .*

PROOF. Let Π be any extended SN P system with generalised input, standard output, and neurons σ_1 , σ_2 and σ_3 . Also, let x be the maximum number of times the output neuron σ_3 is permitted to fire and let q and r be the maximum value for b and p respectively, for all $E/s^b \rightarrow s^p; d$ in Π .

We begin by explaining how the activity of σ_3 may be simulated using only the states of T_Π (i.e. no workspace is required to simulate σ_3). Recall that the applicability of each rule is determined by a regular expression over a unary alphabet. We can give a single regular expression R that is the union of all the regular expressions for the firing rules of σ_3 . This regular expression R determines whether or not there is any applicable rule in σ_3 at each timestep. Figure 4 gives the deterministic finite automata G that accepts $L(R)$ the language generated by R . During a computation we may use G to decide which rules are applicable in σ_i by passing an s to G each time a spike enters σ_3 . However, G may not give the correct result if spikes leave the neuron as it does not record spikes leaving σ_i . Thus, using G we may construct a second machine G' such that G' records the movement of spikes going into and out of the neuron. G' is constructed as follows: G' has all the same states (including accept states) and transitions as G along with an extra set of transitions that record spikes leaving the neuron. This extra set of transitions are given as follows: for each transition on s from a state g_i to a state g_j in G there is a new transition on $-s$ going from state g_j to g_i in G' that records the removal of a spike from σ_3 . By recording the dynamic movement of spikes, G' is able to decide which rules are applicable in σ_3 at each timestep during the computation. G' is also given in Figure 4. To simulate the operation of σ_3 we emulate the operation of G' in the states of T_Π . Note that there is a single non-deterministic choice to be made in G' . This choice is at state g_u if a spike is being removed ($-s$). It would seem that in order to make the correct choice in this situation we need to know the exact number of spikes in σ_3 . However, we need only store at most $u + yq$ spikes. The reason for this is that if there are $\geq u + yq$ spikes in σ_3 , then G' will not enter state g_{u-1} again. To see this, note that σ_3 spikes a maximum of y times using at most q spikes each time, and so once there are $> u + yq$ spikes the number of spikes in σ_3 will be $> u - 1$ for the remainder of the computation. Thus, T_Π simulates the activity of σ_3 by simulating the operation of G' and encoding at most $u + yq$ spikes in its states.

In this paragraph we explain the operation of T_Π . Following this, we give an analysis of the space complexity of T_Π . T_Π has 4 tapes including an output tape, which is initially blank, and a read only input tape. The tape head on both the input and output tapes is permitted to only move right. Each of the remaining tapes, tapes 1 and 2 simulate the activity of the neurons σ_1 and σ_2 , respectively. These tapes record the number of spikes in σ_1 and σ_2 . A timestep of Π is simulated as follows: T_Π scans tapes 1 and 2 to determine if there are any applicable rules in σ_1 and σ_2 at

that timestep. The applicability of each neural rule in Π is determined by a regular expression and so a decider for each rule is easily implemented in the states of T_Π . Recall from the previous paragraph that the applicability of the rules in σ_3 is already recorded in the states of T_Π . Also, T_Π is non-deterministic and so if more than one rule is applicable in a neuron T_Π simply chooses the rule to simulate in the same manner as Π . Once T_Π has determined which rules are applicable in each of the three neurons at that timestep it changes the encodings on tapes 1 and 2 to simulate the change in the number of spikes in neurons σ_1 and σ_2 during that timestep. As mentioned in the previous paragraph any change in the number of spikes in σ_3 is recorded in the states of T_Π . The input sequence of Π may be given as binary input to T_Π by placing it on its input tape. Also, if at a given timestep a 1 is read on the input tape then T_Π simulates a spike entering the simulated input neuron. At each simulated timestep, if the output neuron σ_3 spikes then a 1 is placed on the output tape, and if σ_3 does not spike a 0 is placed on the output tape. Thus the output of Π is encoded on the output tape when the simulation ends.

In a two neuron system each neuron has at most one out-going synapse and so the number of spikes in the system does not increase over time. Thus, the total number of spikes in neurons σ_1 and σ_2 can only increase when σ_3 fires or a spike is sent into the system from the environment. The input is of length n , and so σ_1 and σ_2 receive a maximum of n spikes from the environment. Neuron σ_3 fires a total of y times sending at most r spikes each time and so the maximum number of spikes in σ_1 and σ_2 during the computation is $n + 2ry$. Using a binary encoding tapes 1 and 2 of T_Π encode the number of spikes in σ_1 and σ_2 using space of $\log_2(n + 2ry)$. As mentioned earlier no space is used to simulate σ_3 , and thus T_Π simulates Π using space of $O(\log n)$. $\square$

It is interesting to note that with a slight generalisation on the system in Theorem 4 we obtain universality. If we remove the restriction that allows the output neuron to fire only a constant number of times then we may construct a universal SN P system with extended rules and only three neurons. Here we define the output of an extended SN P system with generalised output to the time interval between the first and second timesteps where exactly x spikes are sent out of the output neuron.

Theorem 5 *Let C_2 be a universal counter machine with 2 counters that completes its computation in time t to give the output value x_o when given the input value x_1 . Then there is a universal extended SN P system Π''_{C_2} with standard input and generalised output that simulates the computation of C_2 in time $O(t + x_1 + x_o)$ and has only 3 neurons.*

PROOF. A graph of Π''_{C_2} is constructed by removing the output neuron σ_5 from the system Π_{C_2} given in the proof of Theorem 2 and making σ_3 the new output neuron of Π''_{C_2} . The rules for Π''_{C_2} are given by the first 3 rows of Table 5 and a diagram of the system is obtained by removing neurons σ_4 and σ_5 from Figure 1 and adding a synapse to the environment from the new output neuron σ_3 . The operation of Π''_{C_2} is identical to the operation of Π_{C_2} with the exception of the new output technique. The output of Π''_{C_2} is the time interval between the first and second timesteps where exactly 2 spikes are sent out of the output neuron σ_3 . $\square$

From the third paragraph of the proof of Theorem 4 we get the following immediate corollary.

Corollary 1 *Let Π be any extended SN P system with only 2 neurons and generalised input and output. Then there is a non-deterministic Turing machine T_Π that simulates the computation of Π in space $O(\log n)$ where n is the length of the input to Π .*

6. Conclusion

The dramatic improvement on the size of earlier small universal SN P system given by Theorems 1 and 3 is in part due to the method we use to encode the instructions of the counter machines our systems simulate. In the systems of Păun and Păun [15] each counter machine instruction was encoded by a unique set of neurons. Thus the size of the system is dependant on the number of instructions in the counter machine being simulated. Some improvement was made by Zhang et al. [18] by showing that certain types of instructions may be grouped together. However, the number of neurons used by the system remained dependant on the number of instructions in the counter machine being simulated. In our systems each unique counter machine instruction is encoded as a unique number of spikes and thus the size of our SN P systems are independent of the number of instruction used by the counter machine they are simulating. The technique of encoding the instructions as spikes was first used to construct small universal SN P systems in [14].

The results from Theorems 2 and 4 give tight upper and lower bounds on the size of the smallest universal SN P system with extended rules. Thus in Theorem 2 we have given the smallest possible universal SN P system with extended rules. The results from Theorem 5 and Corollary 1 give tight upper and lower bounds on the size of the smallest universal SN P systems with extended rules and generalised output. Thus, Theorem 5 gives the smallest possible universal SN P system with extended rules and generalised output.

The lower bounds given in Theorem 4 are also applicable to standard SN P systems and thus give a lower bound of 4 neurons for the smallest possible standard system that is universal. However, when compared with extended systems the rules used in standard SN P systems are quite limited, and so it seems likely that this lower bound of 4 neurons can be increased. Note that here and in [15,18] the size of a universal SN P system is measured by the number of neurons in the system. However, the size of an SN P system could also be measured by the number of neural rules in the system.
